INFORMATION IN THIS DOCUMENT IS PROVIDED IN CONNECTION WITH INTEL PRODUCTS. NO LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE, TO ANY INTELLECTUAL PROPERTY RIGHTS IS GRANTED BY THIS DOCUMENT. EXCEPT AS PROVIDED IN INTEL'S TERMS AND CONDITIONS OF SALE FOR SUCH PRODUCTS, INTEL ASSUMES NO LIABILITY WHATSOEVER AND INTEL DISCLAIMS ANY EXPRESS OR IMPLIED WARRANTY, RELATING TO SALE AND/OR USE OF INTEL PRODUCTS INCLUDING LIABILITY OR WARRANTIES RELATING TO FITNESS FOR A PARTICULAR PURPOSE, MERCHANTABILITY, OR INFRINGEMENT OF ANY PATENT, COPYRIGHT OR OTHER INTELLECTUAL PROPERTY RIGHT.

UNLESS OTHERWISE AGREED IN WRITING BY INTEL, THE INTEL PRODUCTS ARE NOT DESIGNED NOR INTENDED FOR ANY APPLICATION IN WHICH THE FAILURE OF THE INTEL PRODUCT COULD CREATE A SITUATION WHERE PERSONAL INJURY OR DEATH MAY OCCUR.

Intel may make changes to specifications and product descriptions at any time, without notice. Designers must not rely on the absence or characteristics of any features or instructions marked "reserved" or "undefined." Intel reserves these for future definition and shall have no responsibility whatsoever for conflicts or incompatibilities arising from future changes to them. The information here is subject to change without notice. Do not finalize a design with this information.

The products described in this document may contain design defects or errors known as errata which may cause the product to deviate from published specifications. Current characterized errata are available on request.

Contact your local Intel sales office or your distributor to obtain the latest specifications and before placing your product order.

Copies of documents which have an order number and are referenced in this document, or other Intel literature, may be obtained by calling 1-800-548-4725, or go to <http://www.intel.com/design/literature.htm>.

Intel processor numbers are not a measure of performance. Processor numbers differentiate features within each processor family, not across different processor families. Go to: http://www.intel.com/products/processor_number/.

This document contains information on products in the design phase of development.

Software and workloads used in performance tests may have been optimized for performance only on Intel microprocessors. Performance tests, such as SYSmark and MobileMark, are measured using specific computer systems, components, software, operations and functions. Any change to any of those factors may cause the results to vary. You should consult other information and performance tests to assist you in fully evaluating your contemplated purchases, including the performance of that product when combined with other products.

Optimization Notice

Intel compilers, associated libraries and associated development tools may include or utilize options that optimize for instruction sets that are available in both Intel and non-Intel microprocessors (for example SIMD instruction sets), but do not optimize equally for non-Intel microprocessors. In addition, certain compiler options for Intel compilers, including some that are not specific to Intel micro-architecture, are reserved for Intel microprocessors. For a detailed description of Intel compiler options, including the instruction sets and specific microprocessors they implicate, please refer to the "Intel Compiler User and Reference Guides" under "Compiler Options." Many library routines that are part of Intel compiler products are more highly optimized for Intel microprocessors than for other microprocessors. While the compilers and libraries in Intel compiler products offer optimizations for both Intel and Intel-compatible microprocessors, depending on the options you select, your code and other factors, you likely will get extra performance on Intel microprocessors.

Intel compilers, associated libraries and associated development tools may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include Intel® Streaming SIMD Extensions 2 (Intel® SSE2), Intel® Streaming SIMD Extensions 3 (Intel® SSE3), and Supplemental Streaming SIMD Extensions 3 (SSSE3) instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors.

While Intel believes our compilers and libraries are excellent choices to assist in obtaining the best performance on Intel and non-Intel microprocessors, Intel recommends that you evaluate other compilers and libraries to determine which best meet your requirements. We hope to win your business by striving to offer the best performance of any compiler or library; please let us know if you find we do not.

About Median Filter

Median Filter sample demonstrates how to use median filter in OpenCL™. This implementation optimizes filtration process using implicit Single Instruction Multiple Data (SIMD) code vectorization performed by build-in OpenCL compiler vectorizer. Data-level parallelism of the underlying algorithm results in additional performance gain. The sample improves the performance of the method and reduces data loads. The following figure illustrates median filtering [1]:

Path

Location	Executable
<INSTALL_DIR>samples\MedianFilter	Win32\Release\MedianFilter.exe - 32-bit executable x64\Release\MedianFilter.exe - 64-bit executable Win32\Debug\MedianFilter.exe - 32-bit debug executable x64\Debug\MedianFilter.exe - 64-bit debug executable

Introduction

Median filter is a non-linear filter that removes noise from an image or a signal. One of the advantages of this method is that it can preserve sharp edges while removing noise. To remove noise, the median filter algorithm processes element patterns of the input image or signal. For each pattern of neighboring elements called *window* or *support*, the algorithm finds the median value that is further used as filtering result for the central element of the window.

Motivation

In general, median filter effect requires a significant number of calculations and color buffer accesses. This sample implementation minimizes color buffer accesses, removes synchronization points, and uses data-level parallelism. This results in significant performance gain and better result quality as compared to applications that use the same filtration technique optimized for traditional GPU architectures. For an example, please see the algorithm implemented for traditional GPUs described in [\[2\]](#).

This sample demonstrates a CPU-optimized implementation of 2D image median filtration, showing how to:

- implement calculation kernels using OpenCL C99
- parallelize the kernels by running several work-groups in parallel
- organize host-device data exchange with final image storage on the hard drive.

Algorithm

The median filter processes each pixel in the image and compares it to its neighbors to determine whether this pixel can represent the window entries. It replaces the central pixel value with the *median* of the pixel values in the window.

To define the median of a window, sort the entries of the window numerically. For windows with an odd number of entries, the median is the value of the middle entry. For windows with an even number of entries, several options are possible.

The following figure illustrates a sample calculation of the median value for a pixel neighborhood:

123	125	126	130	140	Neighborhood values: 115, 119, 120, 123, 124, 125, 126, 127, 150 Median value: 124
122	124	126	127	135	
118	120	150	125	134	
119	115	119	123	133	
111	116	110	120	130	

This example illustrates a 3×3 square window. As the central pixel value of 150 does not represent the surrounding values well, it is replaced with the median value of 124. Please note that larger windows produce greater smoothing.

The advantage of the median filtering is that unrepresentative pixels in a window cannot have significant effect on the median value. Since the median value must be an actual value of one of the window entries, the median filter does not create new unrealistic pixel values when the filter processes an edge region. Thus, median filtering permits to preserve sharp edges. For details, see [3].

OpenCL™ Implementation

This sample applies the following algorithm stages to a 2D image:

- 3x3 pixels patch load
- partial bitonic sorting
- result storage in 4-channel 32-bit integer format.

In this implementation, `MedianFilterBitonic` OpenCL™ kernel of `MedianFilter.cl` file uses partial bitonic sorting to perform median filtering. Every input array row corresponds to a unique global ID that the kernel uses for their identification. The full median filtering sequence consists of OpenCL kernel call performed in `ExecuteMedianFilterKernel()` function of `MedianFilter.cpp` file.

This algorithm implementation consists of the [Pixels Load](#) and [Partial Sort](#) parts.

Pixels Load

This sample uses 32-bit red, green, blue, and alpha (RGBA) pixels, with 8-bit unsigned `char` values representing pixel individual color channel. For further processing, $3 \times 3 = 9$ pixels are preloaded into temporary storage.

Partial Sort

This sample uses an algorithm that operates on 3×3 box-shaped support and performs partial sort to find the fifth sorted value out of $3 \times 3 = 9$ values. Partial sort performs 19 MIN and 20 MAX operations to find median value for 3×3 support for each color channel. The algorithm operates with 32-bit unsigned integer values. For details on this algorithm, please see [\[4\]](#) and [\[5\]](#).

Understanding OpenCL Performance Characteristics

Benefits of Implicit Compiler Vectorization

The kernel structure enables implicit vectorization performed by Intel OpenCL compiler when work-group size is multiple of 4. Consequently, you can achieve ~2x speedup for the current versions of kernel and vectorizer.

Work-group Size Considerations

You can specify any work-group size for the kernel. However, OpenCL implementation of the median filter achieves peak performance for 1024×1024 two-dimensional array with work-group size ranging from 4 to 64 elements.

Limitations

The current version of the sample requires scalar data types and a fixed kernel size (3×3 median filter).

Future Work and Enhancements

The sample performs all calculations in integer values. Each image pixel consists of four 32-bit integer values representing RGBA image channels. You can improve this sample performance by introducing the following:

- arbitrary window size
- alternative implementation of sorting part (binary search)
- further filter extension (bilateral filter)
- more compact data representation (`uchar`).

Project Structure

This sample project has the following structure:

- `MedianFilter.cpp` - the host code, with OpenCL initialization and processing functions. This source file also includes native implementation of the algorithm.
- `MedianFilter.cl` - source code of the OpenCL median filter kernel.
- `MedianFilter.vcproj` - Microsoft Visual Studio* 2008 project file.

APIs Used

This sample uses the following APIs:

- `clKcreateKernel`
- `clCreateContextFromType`
- `clGetContextInfo`
- `clCreateCommandQueue`
- `clCreateProgramWithSource`
- `clBuildProgram`
- `clCreateBuffer`
- `clSetKernelArg`
- `clEnqueueNDRangeKernel`
- `clEnqueueReadBuffer`
- `clReleaseMemObject`
- `clReleaseKernel`
- `clReleaseProgram`
- `clReleaseCommandQueue`
- `clReleaseContext.`

Reference (Native) Implementation

Reference implementation is done in `ExecuteMedianFilterReference()` routine of `MedianFilter.cpp` file. This is single-threaded code that performs exactly the same median filtering sequence as OpenCL implementation, but uses conventional C nested loop.

Controlling the Sample

The sample executable is a console application. You can set the input array size using command line arguments.

If you do not specify the array size, the sample uses the default value of $1024 \times 1024 = 1048576$ items.

- h command line argument prints help information;
- h **<height>** command line argument setups input array size height;
- w **<width>** command line argument setups input array size width.
